

ECN 102: Analysis of Economics Data

Midterm Exam SS1 2025

Remy Beauregard, Department of Economics, UC Davis

This exam consists of 5 short-answer questions (with sub-parts) and 5 multiple choice questions. You will have a maximum of 100 minutes to complete this exam. No additional time may be taken without prior accommodation. Show all work to receive full credit. You may use only the calculators provided by the instructor. For questions requiring computation, it suffices to express your final answer with 2 decimal places. There is a formula sheet and scratch paper provided at the end of this exam. You may remove these pages and discard them after the exam. If you plan to use any of these extra pages for your final answers, please write your name and student ID at the top of each to ensure they are not lost.

This exam is worth 70 points.

Question 1: Summary Statistics [15 points]

Suppose we are using a dataset that contains one large positive outlier (i.e. one value far greater than all other values). We know this value is not a mistake and so do not want to drop it from our sample. However, we do want to use the proper statistics to describe our data with this outlier:

- What statistic of central tendency should we use for this data? Why? [3 points]
- What statistic of spread should we use for this data? Why? [3 points]
- What can we infer about the skewness of this dataset from the description above? What can we infer about the mean of the data relative to the median? [3 points]
- Can we expect this dataset to be normally distributed based on the information above? Please justify your answer. [3 points]

- e) Suppose we really want to work with a normal distribution for our analysis. Is there anything we could do to our dataset above to make it appear more normally distributed? If we are successful, what name would we give the resulting (more normal-looking) distribution? [3 points]

Question 2: Summation Notation [4 points]

Please rewrite (*but do not simplify*) the following quantities using summation notation ($\sum$) with index i :

- a) [2 points]

$$3x_1 + 3x_2 + 3x_3 + 3x_4$$

- b) [2 points] (*Hint: the formula to find the i^{th} odd integer is $2i - 1$*)

$$1 + 3 + 5 + 7 + 9 + 11$$

Question 3: Univariate Inference [8 points]

Suppose we wish to learn about the population mean of a series but only know the information given below. For each of the following scenarios, please give (1) whether or not we would need to conduct inference to answer our question and (2) the name and formula of the test statistic we would construct (if doing inference):

a) We know $\bar{x}$, $s_{\bar{x}}$, n and hypothesize μ_0 . [2 points]

b) We know $\bar{x}$, $\sigma_{\bar{x}}$, n and hypothesize μ_0 . [2 points]

c) We know $\bar{x}$, σ_x , n and hypothesize μ_0 . [2 points]

d) We know $\bar{x}$, σ_x , n , μ and hypothesize μ_0 . [2 points]

Question 4: More Univariate Inference [15 points]

We are given the following output from Stata:

(1978 automobile data)

```
invttail(60,0.05)=1.6706489
invttail(60,0.025)=2.0002978
invttail(59,0.05)=1.671093
invttail(59,0.025)=2.0009954
invttail(58,0.05)=1.6715528
invttail(58,0.025)=2.0017175
```

Suppose we then use the `summarize` command to obtain the following results for the three variables below:

Variable	Obs	Mean	Std. dev.	Min	Max
price	60	5907.467	2577.946	3291	13594
mpg	60	21.66667	6.001883	12	41
weight	60	2923.833	769.0917	1760	4840

a) Which of the three variables has the *lowest* dispersion (spread relative to its mean)? [2 points]

b) Provide a 90% CI for the mean of *mpg*. Interpret this range in words. [3 points]

c) The claim is made that the average price of a car in 1978 is below \$6000. Using our sample, test this claim at the 5% significance level. Clearly state your null and alternate hypotheses, your test statistic, and your conclusion. [5 points]

d) The claim is made that the average weight of a car in 1978 is different from 3500 pounds. Using our sample, test this claim at the 5% significance level. Clearly state your null and alternate hypotheses, your test statistic, and your conclusion. [5 points]

Question 5: Bivariate Inference [18 points]

a) Write down the population model (equation) for a bivariate regression of y on x if our assumptions about linearity, unbiasedness, homoskedasticity, and independence hold. [2 points]

b) Assuming our four population assumptions hold, complete the statement (fill in the blanks) for how we expect b_2 to be distributed. [5 points]

$$\frac{b_2 - \text{---}}{\text{---}} \sim N(0, 1) \text{ when } n > \text{---}$$

Suppose we now run a regression and obtain these results:

Source		SS		df	MS	Number of obs	=	60
-----+-----								
Model		80799680.8		1	80799680.8	F(1, 58)	=	15.05
Residual		311302776		58	5367289.24	Prob > F	=	0.0003
-----+-----								
						R-squared	=	0.2061
						Adj R-squared	=	0.1924
Total		392102457		59	6645804.35	Root MSE	=	2316.7

price		Coefficient	Std. err.	t	P> t	[95% conf. interval]
-----+-----						
mpg		-194.9806	50.25323	-3.88	0.000	-295.5733 -94.38778
_cons		10132.05	1129.152	8.97	0.000	7871.802 12392.29

c) Write down the sample regression model we have estimated (with proper variable names).
[3 points]

d) Suppose we are worried Stata made a mistake computing our R-squared value (0.2061).
Verify this calculation using other information from the regression output. [2 points]

e) Suppose we are worried Stata made a mistake computing the default t-statistic for b_2 (-3.88). Verify this calculation using other information from the regression output. [2 points]

f) What will $\sum_{i=1}^n e_i$ equal for regression? What property will $\sum_{i=1}^n e_i^2$ have? [2 points]

g) Suppose we standardized both our series X and Y and reran the regression above. If we now obtain a b_2 value of -0.45 , what does that tell us about r_{xy} ? Interpret this value. [2 points] **BONUS:** What is the value of $\frac{s_{price}}{s_{mpg}}$? [+2 points]

Multiple Choice [2 points each]

Suppose we know a r.v. $X \sim (16, 16)$, draw 16 samples of size 36 (each), and compute 16 sample means.

MC 1

What would we expect the population **mean** of the distribution of sample means to be equal to?

a) $\sqrt{16} = 4$

- b) 16
- c) $\frac{16}{16} = 1$
- d) $\frac{\sqrt{16}}{16} = \frac{1}{4}$
- e) $\sqrt{\frac{16}{16}} = 1$

MC 2

What would we expect the population **variance** of the distribution of sample means to be equal to?

- a) 16
- b) $\frac{16}{36} = \frac{4}{9}$
- c) $\frac{16}{16} = 1$
- d) $\sqrt{\frac{16}{16}} = 1$
- e) $\sqrt{\frac{16}{36}} = \frac{2}{3}$

MC 3

How would we expect our sample means to be **distributed** and why?

- a) Normally distributed because X is normally distributed
- b) Normally distributed by the CLT because we drew $16 < 30$ samples
- c) NOT normally distributed by the CLT because we drew $16 < 30$ samples
- d) Normally distributed by the CLT because our sample size per draw was $36 > 30$
- e) NOT normally distributed by the CLT because our sample size per draw was $36 > 30$

MC 4

What **range** would we expect to contain roughly 99.7% of the values of sample means?

- a) $16 \pm 3 \times 16$
- b) $16 \pm 3 \times \sqrt{16}$
- c) $16 \pm 3 \times \frac{16}{16}$
- d) $16 \pm 3 \times \frac{16}{36}$
- e) $16 \pm 3 \times \sqrt{\frac{16}{36}}$

MC 5

Which of the following is **true** about the population standard deviations of X and $\bar{X}$?

- a) $\sigma_{\bar{x}} \geq \sigma_x$ always
- b) $\sigma_{\bar{x}} = \sigma_x$ always
- c) $\sigma_{\bar{x}} \leq \sigma_x$ always
- d) The answer will depend on our sample size n
- e) None of the above
